CFS-NEES Building Structural Design Narrative¹

INTRODUCTION

The NSF sponsored CFS-NEES¹ project R-CR: Enabling Performance-Based Seismic Design of Multi-Story Cold-Formed Steel Structures project was undertaken to study the behavior, particularly seismic behavior, of light-framed structures using cold-formed steel cee-sections as the primary gravity load carrying elements with wood structural panel diaphragms and shearwalls as the primary lateral load resisting system.

Devco Engineering, Inc. was selected to develop design calculations and drawings for the structure based on criteria determined by the research team. Input on the details of design was also sought from industry professionals through the Industry Advisory Board (IAB)². The details developed in the design phase will be studied via component and full-scale shake table testing of the structure.

This report discusses the design of the gravity and lateral systems for the CFS-NEES building. Specific calculations and drawings are attached herewith as appendices for reference.

Design Criteria

Design of the structure was based on a site in Orange County, California. Gravity and lateral loads were determined per the 2009 edition of the International Building Code (IBC) based on this location.

For member sizing, the "North American Specification for the Design of Cold-Formed Steel Structural Members", 2007 edition (AISI S100-07) was used. Member callouts were based on SSMA/SFIA criteria. Shearwall and diaphragm design was based on the "North American Standard for Cold-Formed Steel Framing – Lateral Design", 2007 edition (AISI S213-07).

Wind and seismic forces were determined based on a location at 520 W. Walnut Blvd, Orange, California (latitude 33.8 degrees; longitude -117.86 degrees).

For simplicity, and consistent with industry standards, allowable strength design (ASD) was used for members and connections not part of the lateral force resisting system (LFRS). For design of the LFRS, load and resistance factor design (LRFD) was used.

Architectural Concept

The architectural concept for the CFS-NEES building was developed by the project team. See Appendix 6 for a rendition of the architectural concept.

¹ See <u>www.ce.jhu.edu/cfsnees</u> for details

² See <u>www.ce.jhu.edu/cfsnees/advisoryboard.php</u> for member list

Calculation Systems and Notations

Calculations were developed using standards employed at Devco Engineering for page numbering and labeling of attached documents. The following describes the system used:

The particular element design being undertaken is double underlined at the top of the first page associated with the design of that element. The criteria used to size the element, for example loading, span lengths and any special considerations follow. Final member or connection selection is double underlined with an arrow on the right hand side of the page.

Computer printouts or other associated documents related to a specific element design are attached behind the hand calculations for that element. These supplemental documents are referenced by a number inside a hexagon on the hand calculations and the same symbol and number can be found in the upper right hand corner of the related printout.

Where spreadsheet printouts are provided in the appendices, black values are labels, blue values are user inputs and red values are calculated within the spreadsheet.

<u>Software</u>

The following software was used in the development of the calculations:

- AISIWIN version 8, Devco Software, Inc. Used for member sizing of simple span members with uniform loads and axial loads were applicable.
- LGBEAMER version 8, Devco Software, Inc. Used for member sizing of more complex span and load conditions.
- Microsoft Excel: Used to develop spreadsheets for lateral analysis and other general purpose calculation tasks.

Member Nomenclature

Member designations were used per SSMA/SFIA standards.

Appendices

Appendices 1-5 attached contain the following:

- Appendix 1: Framing Member Design
- Appendix 2: Seismic Lateral Analysis

Appendix 3: Shearwall and Diaphragm Analysis and Design

Appendix 4: Lateral System Design – Supplemental Calculations

Appendix 5: Design Drawings dated 10/31/11

Appendix 6: Architectural concept drawings

Structural Design Summary

Gravity System

Based on input from the IAB, a 'ledger framing' system was chosen rather than traditional platform framing. According to the IAB, ledger framing which attaches floor and roof joists to the inside flanges of the load-bearing studs via a combination of track and clip angles is currently the dominant method of construction. Studs are broken at the top of each floor level and capped with a track. Walls above are stacked on the lower wall top track. See Appendix 5, details 1 and 2/SF4.40.

Roof Joists

Roof joists were designed as simple span members with uniform loading. End rigidity of the attachment to the stud walls was not considered in the roof joist design. Design loads included 20 psf dead load, 20 psf live load and wind uplift per IBC requirements. Note that for the effective wind area associated with the joist spans for this building, maximum corner wind uplift was calculated at 14.1 psf and thus was not a significant concern in the design.

Roof joist deflection was limited to L/240 for dead load and L/180 for total loads. For distortional buckling, k_{ϕ} was conservatively taken as zero. Had additional flexural strength been required, the k_{ϕ} value appropriate for the joists selected and OSB sheathing on the compression flange could have been used.

Based on these loads and a maximum clear span of 22 feet, 1200S200-54 joists at 24 inches on center were selected. The compression flange of the joists was considered to be continuously braced via attachment of sheathing. In accordance with industry standards, two rows of bridging were specified in order to minimize joist rotation.

Because the web height-to-thickness for the selected joists exceeded 200, web stiffeners were required at member ends. Stiffening was accomplished with clip angles screwed to the joist and to the rim (ledger) track. This method transfers the reaction from the joist web to the support in direct shear rather than bearing, thus precluding web crippling failure in the joists.

Rooftop mechanical units each weighing up to 600 lb were anticipated. Design of the joists for support of these units was based on the load being distributed to at least two joists with two 150 lb point loads supported by any individual member. Based on these loads, back-to-back 1200S200-54 joists were specified at mechanical unit supports.

Roof joist design, including sizing of joists at mechanical units and connection of joists to exterior walls can be found in Appendix 1, page R-1. Drawings related to roof joists can be found in Appendix 5, sheets SF4.02, SF4.20 and SF4.40.

Floor Joists

In addition to the standard 18 psf dead load to account for framing, sheathing, flooring and the like, a 15 psf partition load was included to account for partitions that may be moved at various times during the structure's life span. Live load for floor joist design varies by location. For example, the typical live load is 50 psf but 80 psf is required at corridors. As such, joists were

designed as simple span members with varying distributed loads. Similar to the roof joists, end rigidity of the connection to the wall was not considered.

Deflection limits of L/240 for total loads and L/360 for live loads were used. For distortional buckling, k_{ϕ} was conservatively taken as zero. Had additional flexural strength been required, the k_{ϕ} value appropriate for the joists selected and plywood sheathing on the compression flange could have been used.

Based on the above, 1200S250-97 joists 24 inches on center were selected. The compression flange of the joists was considered to be continuously braced via attachment of sheathing. Two rows of bridging were specified in order to minimize joist rotation. In addition, due to the high end reactions and relatively short bearing length, web stiffeners were required at joist ends. Stiffening was accomplished in the same way as at the roof, but with additional fasteners required for the higher loads.

At the clerestory opening, single track headers were designed to carry floor joist loads to carrier joists on either side of the opening. A 1200T200-68 was chosen for the 8'6" span. Carrier joists were designed for a distributed load equal to one half of that used at typical joists in combination with the concentrated loads from the headers on each side of the opening. Single 1200S350-97 carriers were selected.

Floor joist analysis and design is found in Appendix 1, pages F-1 and F-2. Drawings for floor joists can be found in Appendix 5, sheets SF4.01, SF4.20 and SF4.40.

Load-bearing Walls

For a desired clear height of framing of 8'0" and 12" deep joists, studs were designed as 9 ft. in length. Code prescribed wind loads, when reduced for area, were less than 15 psf. As such, a slightly conservative value of 15 psf wind load was used for stud design.

Studs above the 2nd floor platform were designed to carry wind load in combination with roof dead and live loads. Load combinations per ASCE 7-05 were used. The total gravity load of 440 lb/stud was used based on the roof joist reactions. Gravity loads were applied at the inboard stud flange, resulting in an end eccentricity of 3 inches to the center of the studs. Since walls will receive gypsum board sheathing on at least one flange, k_{ϕ} for distortional buckling was taken as zero per CFSEI Technical Note G100-08. Based on these criteria, 600S162-33 studs at 24 inches on center were chosen. The studs were acceptable with either sheathing bracing, or discrete bracing near mid-height. Since some tests may be performed without interior sheathing, discrete bridging (noted as CRC, or cold-rolled channel in the calculations) will be required for these tests.

With the stud size known, the connection of the roof joists to the wall was designed. The connection was designed for shear due to gravity loads plus tension due to outward acting wind loads (suction) on the wall studs.

In order to allow the roof diaphragm to extend over the top of the level 2 walls, the parapet was designed as a free-standing cantilever. Track and fasteners were chosen to resist the associated overturning forces.

Walls running perpendicular to the joists transfer out of plane lateral forces to the diaphragm via their connection to the joists. However, for walls parallel to the joists, transferring out of plane wall forces into the diaphragm is accomplished via a direct connection of the wall to the diaphragm sheathing. For plywood to steel connections, allowable screw forces were based on the American Plywood Association publication APA E830D "Technical Note: Fastener Loads for Plywood – Screws", dated August 2005.

Lower level walls were designed similarly to the upper level walls except that in addition to roof gravity loads, floor gravity loads were also considered. Gravity loads from the roof and wall above were considered concentric. Gravity loads from floor joists were applied at the inboard stud flange, thus introducing an eccentricity of half the stud width or 3 inches. On this basis, 600S162-54 studs @ 24 inches on center with discrete bridging at mid-height were chosen.

With the stud size known, the connection of the floor joists to the wall was designed. The connection was designed for shear due to gravity loads plus tension due to outward acting wind loads (suction) on the wall studs.

At the stair clerestory the carrier joists apply concentrated vertical loads to the 1st floor wall studs. Based on the maximum load from the carrier joists and from the roof and wall above, it was determined that two 600S162-54 studs would be required along with additional fasteners from the rim track to the studs.

At the northwest exit stair, the 2nd floor joists are supported by an interior wall. The interior wall is subjected only to 5 psf partition pressure and does not support roof gravity loads. Accordingly, these studs were sized as 362S162-54 at 24 inches on center with bridging at 48 inches on center.

Additionally at the northwest exit stair, the exterior wall studs span the full 18' 0" height to the roof joists. These studs support only roof gravity loads. On this basis, the studs were sized as 600S162-54 at 24 inches on center with bridging at 48 inches on center.

Design of structural walls can be found in Appendix 1, pages W-1 through W-5. Drawings depicting the load-bearing walls can be found in Appendix 5, sheets SF4.20, SF4.30 and SF4.40.

2nd Floor Wall Openings

To support loads around window and door openings, headers, sill and jambs were sized. A maximum opening width of 8' 0" was considered. For windows, openings were considered to be 4' 0" tall with a sill height of 2' 6".

For openings at the 2nd floor, the perimeter rim track or joists were found to have sufficient capacity to carry gravity loads over the opening. As such, no additional gravity header was specified.

Header and sill tracks were sized as 600T150-33 to carry a 15 psf lateral load from jamb-tojamb. The connection of these members to the jamb studs was designed to support 196 lb of lateral shear. Per AISI S100-07 section E4, The shear capacity of a #10 sheet metal screw in 33-mil steel is 177 lb/screw. As such, (4) #10 as specified is, by observation, adequate.

Jamb studs were sized based on the lateral reactions from the header and sill as well as the eccentric vertical reaction from the rim track or joist above. To account for the eccentric nature of gravity loads, a moment couple was included based on 3 inches of eccentricity and a 12 inch deep member. An option for using two 600S162-33 or a single 600S162-54 jamb was provided. Interconnection of the two-member configuration was designed per AISI S100-07 D1.2.

Design of the jamb/rim track connection considered the concentrated shear due to gravity loads as well as the top of jamb lateral reaction from the jamb analysis. Screw quantity was determined based on minimum 33-mil jambs.

Design of openings in the 2nd floor walls can be found in Appendix 1, pages W-6 and W-7. Framed opening drawings can be found in Appendix 5, sheet SF4.50.

1st Floor Wall Openings

For the long side of the structure, the 1200T200-97 rim track above openings was analyzed and found to be sufficient to carry gravity loads over openings up to 6' 6" in width. For larger openings, two 1200S250-97 were specified. The two 1200S250-97 header members were also specified for openings where clerestory carriers were supported.

For the short side of the structure, the maximum opening was 6' 0" in width. As such, the 1200S250-97 end joist could easily carry the gravity loads over the opening.

Head and sill tracks were sized as 600T150-54 for 15 psf lateral pressures.

Jambs were designed with considerations similar to those at the 2nd level, but with additional gravity loads from the structure above. On this basis, an option for two 600S162-54 or a single 600S200-68 were specified.

For large openings where gravity loads were exceptionally high, rather than rely on the screw shear to support the entire gravity loads, trimmer studs (studs immediately below the header that support header gravity loads as axial loads) were designed to provide a bearing type support for the header. 600S162-54 trimmers in combination with 600S162-54 king, or jamb studs were specified.

Design of openings in the 2nd floor walls can be found in Appendix 1, pages W-8 through W-10. Framed opening drawings can be found in Appendix 5, sheet SF4.50.

Lateral System

Because testing will be based on shake-table simulated seismic forces, the design of the lateral system focused on seismic design.

Lateral forces were determined based on mapped short period spectral response acceleration parameter, S_s , and mapped 1-second spectral response acceleration parameter, S_1 for the location described previously. Site Class D was chosen as is typical for sites in the vicinity of this project. For the office occupancy chosen, $I_E = 1.0$ was used.

Lateral resistance was provided by wood structural panel shearwalls. For this system, the following parameters were derived from ASCE 7-05 Table 12.2-1:

Response Modification Coefficient, R = 6.5 Overstrength Factor, Ω_0 = 3 Deflection Amplification Factor C_d = 4

The resulting base shear coefficient was calculated as $C_s = 0.143$.

The effective seismic weight, W used in ASCE 7-05 Eq'n 12.8-1 was based on estimated weights of roof, floor and exterior walls. A 1200 lb allowance for roof top MEP was included. In addition, per ASCE 7-05 section 12.7.2, a 10 psf allowance for partitions was included on the 2nd floor. Reduced seismic weight due to stair openings in the 2nd floor were not considered as the weight of attached stair elements would likely counteract any reduction in floor mass. A total seismic weight of approximately 78 kips was determined; resulting in a seismic base shear force of approximately 11 kips.

The vertical distribution of the calculated shear was based on ASCE 7-05 section 12.8.3. The design shear forces at the roof and 2^{nd} levels were determined to be roughly 6.5 and 4.5 kips respectively.

Calculation of C_s , W and the seismic shear at each level is shown in Appendix 2, page 1 and Appendix 1, sheet L-2.

Shearwalls

Based on the proposed location of windows and doors, shearwall locations were selected on each of the (4) perimeter walls. Both Type I and Type II shearwalls were investigated. However, for this structure, the Type II shearwalls did not, in the opinion of the investigators and the IAB, provide a significant benefit. As such, Type I shearwalls were selected throughout.

The size and location of shearwalls on each side of the building varied. As such, the horizontal distribution of shear was determined based on an estimate of shearwall stiffness. Shearwall stiffness was estimated based on AISI S213-07 Eq'n C2.1.1. Note that shearwall stiffness determined using this method varies with applied load. As such, preliminary estimates of stiffness based on a nominal 1000 lb of shear force were adjusted by trial and error until reasonable deflection compatibility was achieved along each line of shearwalls. Spreadsheets were developed to allow interactive design of the shearwall with changing stiffness. See Appendix 3, sheet 1 for the initial estimate of horizontal shear distribution along each line of shear. Appendix 3, sheet 2 provides the adjusted values of shear distribution as determined by trial and error.

Based on the force distribution, shearwalls were selected per the procedures of AISI S213-07. OSB sheathing was selected on the basis of economy of OSB and on the fact that for 54-mil and heavier framing, a fixed maximum aspect ratio of 2:1 applies to Structural 1 sheathing but not to OSB. The typical 2nd floor stud framing was specified as 33-mil, but in order to meet strength requirements 54-mil chord studs were selected. Also minimum 43-mil top and bottom track were specified. Therefore, shear values applicable to 33-mil (upper level) or 54-mil (lower

level) framing members were used. Per Table C2.1-3 of AISI S213-07, for edge fasteners at 6 inches on center, the nominal shear strength of the assembly selected was 700 lb/ft (upper level) and 825 lb/ft (lower level). Analysis of the individual shearwalls is found in Appendix 3, sheet 2.

ASCE 7-05 Table 12.12-1 limits seismic story drift to $0.025h_{sx}$ for the type of structure contemplated where h_{sx} is the story height. Drift was determined based on AISI S213-07 Eq. C2.1-1 and found to be within this limit for each wall. The data indicates that displacement is dominated by the non-linear term and the anchor/hold-down term of Eq. C2.1-1. For the upper level shearwalls, the anchor/hold-down term was estimated as no data was available for the system used that includes strap elongation as well as fastener slip. For the lower level shearwalls, the anchor/hold-down term was based on data published by the hold-down manufacturer. Displacement analysis can be found in Appendix 3, sheet 3. It should be noted that this displacement is based on the stiffness only of the shearwalls and does not account for additional stiffness provided by non-structural wall panels or the rigidity of the wall to floor connections.

For ease of reference in calculations per Appendix 2 shearwalls were labeled based on their location on the structure. For example, shearwall L2N1 is the first Level 2 shearwall (L2) located on the north side (N1). Note that the analysis of shearwall L1E2 was based on a length of 6 feet while drawings indicate an 8 foot length. The 8 foot length was used based on the window locations to avoid an awkward sheathing infill adjacent to the windows. Because the design is somewhat conservative, calculations were not revised.

See Appendix 5, sheets SF4.00, SF4.10, SF4.11 and SF4.30 for shearwall drawings. Appendix 5, sheet SF4.00 indicates the direction of north used in the calculations.

Shearwall Chord Studs

Shearwall chords were designed for load combinations per ASCE 7-05, section 2.3.2 including dead, live and both lateral and vertical seismic loads. Eccentric moment due to both gravity (ledger on inside face of stud) and seismic (shear panels on outside face of stud) loads were included. Chords were sized based on basic LRFD load combinations in addition to the strength requirements of AISI S213-07, C5.1.2. Chord stud strength was checked at the minimum of the amplified seismic load, or the maximum seismic load the system can deliver as allowed in AISI S213-07. Based on this analysis, two 600S162-54 back-to-back chords were selected for both the 1st and 2nd levels. Note that one chord stud beam-column interaction value of 1.028 was calculated. Based on the minor level of the overstress and the presence of sheathing that is unaccounted for in the analysis, this was considered acceptable. Chord analysis can be found in Appendix 3, sheet 4.

Shearwall ties and hold-downs were sized in accordance with the requirements of AISI S213-07, C5.1.2. Resisting dead load was reduced for vertical seismic force per ASCE 7-05, 12.4.2.3.

Near the northwest exit stair, the shearwall encroached into the balloon framed area at the stair opening. In order to retain the 2-story design typical throughout the remainder of the structure, the portion of the balloon wall used for shear resistance was framed with 'stacked studs'. The tracks between the 1st and 2nd floor wall studs were sized to resist out of plane lateral forces

between the edge of the 2nd floor diaphragm and a jamb stud on the opposite end of the shearwall. A full height 2-story jamb stud was sized to resist these out-of-plane forces as well as act as a chord stud for the shearwall. Note that since the outer stud of the jamb/chord is continuous, no chord tie was required between the 2nd and 1st floors in this location. The design of this system can be found in Appendix 4, sheets SW-1 through SW-2. Drawings for the shearwall chord studs can be found in Appendix 5, sheet SF4.30.

Ties and Hold-downs

For the 2^{nd} floor ties, a strap system was chosen to transfer forces from the 2^{nd} floor chords to the 1^{st} floor chords. To avoid crushing the plywood that runs between the bottom track at the 2^{nd} floor and the top track of the 1^{st} floor, straps were sized for both compression and tension. An unbraced length, KL = 3 inches was conservatively used for the compression analysis based on a maximum 3 inch vertical spacing between upper and lower fasteners. Strap design considered both yielding of the gross section and fracture of the net section. For net section fracture, area was reduced for a maximum of two screw holes based on the design utilizing two vertical rows of fasteners. Both LRFD level forces as well as the minimum of amplified seismic and maximum seismic force the system can deliver were considered in sizing the straps and fasteners.

First floor hold-downs were designed for the same load as 2nd floor ties. However, since a proprietary hold-down was selected, data provided by the manufacturer was used for hold-down strength and fastener requirements. Hold-down analysis can be found in Appendix 3, sheet 5 and Appendix 4 sheet SW-3. Tie and hold-down drawings can be found in Appendix 5, sheet SF4.30.

Shear Anchors

Transfer of 2nd floor shear forces to 1st floor shearwalls is accomplished via screw fasteners between the 2nd floor base track and the 1st floor top track. These fasteners pass through the 2nd floor diaphragm. As such, fasteners with spacing to match the edge fasteners for 2nd floor shearwalls were selected.

For the 1st floor shear anchors, the initial design was based on the notion of a concrete foundation and anchors were sized for the maximum in-plane shear force within a shearwall. However, it is likely that this design will be revised in favor of a steel foundation and alternate anchors will be required. Shear anchor analysis can be found in Appendix 4, sheet SW-4. Shear anchors are shown in Appendix 5, sheet SF4.30.

Diaphragms

Per ASCE 7-10, section 12.3.1.1, diaphragms were idealized as flexible.

Roof and floor diaphragms were designed for the higher of the maximum total roof shear and the minimum diaphragm shear required by ASCE 7-05, Eq. 12.10-2. Diaphragm capacity was determined per AISI S213-07, Table D2-1.

On this basis, an unblocked minimum 7/16 inch OSB diaphragm with fasteners at 6 inches on center at supported edges and 12 inches on center in the field was selected for the roof. For the 2nd floor diaphragm, minimum 23/32 inch unblocked structural panels with fastening to match the roof were selected. Note that the 2nd floor diaphragm has holes at the clerestory and exit

stairs. The reduced diaphragm length in these areas was accounted for. Roof diaphragm analysis and design can be found in Appendix 3, sheet 6 and Appendix 4, page D-1.

Diaphragm perimeter members were sized for the maximum value of drag force supplied to the shearwalls and diaphragm chord forces based on a beam analogy with the chords acting as the tension and compression elements similar to beam flanges. Diaphragm collectors and chords in structures braced by light framed shearwalls are excluded from overstrength requirements per ASCE 7-05, 12.10.2.1 exception 2. As such, only the LRFD level forces were considered in the design of the collectors, chords and their connections. For both the roof and 2nd floor diaphragms, the typical perimeter members used for gravity support were found to be adequate as collectors and chords. Floor diaphragm analysis and design can be found in Appendix 3, sheet 7 and Appendix 4, page D-2.

Chord and collector splices will be required at the long sides of the buildings due to the length of the walls versus standard lengths of track sections. Based on the calculated chord and collector forces, splices were designed. These calculations can be found in Appendix 4, pages D1 and D2.

The north exit stair creates an opening in the 2nd floor diaphragm. To ensure that diaphragm forces generated in the sub-diaphragm south of the stair opening are transferred to the main 2nd floor diaphragm, tension straps and solid blocking were added. Calculations for the blocking and attachments can be found in Appendix 4, page D3. Drawings for this reinforcing can be seen in Appendix 5, sheet SF4.01.

The 2nd floor clerestory opening also requires reinforcing. Reinforcing design was based, conservatively, on a cantilever beam model for piers on each side of the opening. The moment couple created by the shear at the end of the cantilevered element is transferred into the 2nd floor diaphragm via strap and blocking. Design of the strap and blocking can be found in Appendix 4, page D4. This reinforcing can be seen Appendix 5, sheet SF4.01

Summary

Based on IBC and AISI requirements, calculations and drawings for the CFS-NEES building were produced. The calculations and drawings are included as appendices herewith. As with any structural design, certain engineering judgments were required. Where such judgments were required, they were made based on basic principles of mechanics and standards common to the design of cold-formed steel structures.

Appendix 3

Shearwall and Diaphragm Analysis and Design

Shearwall Relative Stiffness - For Horizontal Distribution

Based on AISI S213-07 C2.1.1

V = 1000 (lb) Nominal value for determining relative stiffness

 $E_s = 2.95E+07$ (psi)

Gt = 77500 (lb/in) Based on IBC Table 2305.2.2, taken conservatively for OSB. Also in the 2005 NDS Manual, Table M9.2.4 (page 65

- $\rho =$ 1.05 Constant 1.85 for ply, 1.05 for OSB
- $\omega_{4=}$ 1.0 Constant for wood structural panels
- $\beta = 660$ Constant 810 for Plywood, 660 for OSB

Notes: 1. 'Table' Shearwall capacity based on AISI S213-07, Tabel C2.1-3 unadjusted for aspect ratio

2. Upper level shearwall capacity based on 33-mil perimeter members

3. Lower level shearwall capacity based on 54-mil perimeter members

4. Sheathing screw size No. 8 Typ

Shearwall Displacements - Type I SW analysis only.

Based on AISI S213-07 C2.1.1

E_s = 2.95E+07 (psi)

- Gt = 77500 (lb/in) Based on IBC Table 2305.2.2, taken conservatively for OSB. Also in the 2005 NDS Manual, Table M9.2.4 (page 65)
- $\rho =$ 1.05 Constant 1.85 for ply, 1.05 for OSB
- $\omega_{4=}$ 1.0 Constant for wood structural panels
- $\beta = 660$ Constant 810 for Plywood, 660 for OSB

Notes: 1. Factored DL = (0.9 - 0.2S_{DS})*DL*(SW Length)/2 : Per ASCE 7-10 12.4.2.3

2. Factored T_{net} is amplified T_{seis} less factored DL (DL factored as noted above)

For compression, applied loads come from Chord Force Analysis
 Factored Cmax/Pn is based on the amplified or maximum load SW can deliver chord forces

5. V_n for screws conservatively taken as 3.75 x the screw shear ultimate (based on minimum from several mfrs). V_n for the assembly per NASPEC E4 is > listed value

6. ϕ for screw connections = 0.5 per NASPEC E4

7. Values are conservatively based on Type I shearwalls.

8. Fracture on net section taken through width less two screw diameters. Fu = 65 ksi for Fy = 50 ksi; Fu = 45 ksi for Fy = 33 ksi

Holdowns & Tension Ties

S/HDU Holdowns

The S/HDU series of holdowns combines performance with ease of installation. The pre-deflected geometry virtually eliminates material stretch, resulting in low deflection under load. Installation using self-drilling tapping screws into the studs reduces installation time and saves labor cost. MATERIAL: 118 mil (10 ga) FINISH: Galvanized INSTALLATION: • Use all specified fasteners. See General Notes. · Use #14 screws to fasten to studs CODES: See page 8 for Code Listing Key Chart.

Pilot holes for manufacturing purposes (Fastener not required) S/HDU

EVALUATION SUBJECT:

HILTI KWIK-PRO SELF-DRILLING SCREWS

1.0 EVALUATION SCOPE

Compliance with the following codes:

- 2006 International Building Code[®] (IBC)
- 1997 Uniform Building Code™ (UBC)

Property evaluated:

Structural

2.0 USES

The Hilti Kwik-Pro Self-drilling Screws are used to connect cold-formed steel members to cold-formed steel members.

3.0 DESCRIPTION

The Hilti Kwik-Pro Self-drilling Screws are self-drilling tapping screws complying with ASTM C 1513, and are case-hardened from carbon steel conforming to ASTM A 510, Grade 1022. The screws have a hex washer head and have an electroplated zinc coating complying with ASTM F 1941, or a proprietary coating. Table 1 provides screw designations, sizes and descriptions of point styles. Screws are supplied in boxes of individual screws, or in collated plastic strips.

4.0 DESIGN AND INSTALLATION

4.1 Design:

Allowable fastener loads using Allowable Stress Design (ASD) for pull-out, pull-over, and shear (bearing) capacity are provided in Tables 2, 3 and 5, respectively. Instructions on how to calculate Load Resistance Factor Design (LRFD) capacities are found in the footnotes of these tables. Table 4 presents the nominal and allowable fastener tension and shear strengths for the screws. For connections subject to tension, the least of the allowable pull-out, pullover, and tension fastener strength of screws found in Tables 2, 3, and 4, respectively, must be used for design. For connections subject to shear, the lesser of the allowable shear fastener strength and shear (bearing) found in Tables 4 and 5, respectively, must be used for design. Connections subject to

combined tension and shear loading must be designed in accordance with Section E4.5 of the AISI – NAS.

The values in the tables are based on a minimum spacing between the centers of fasteners of three times the diameter of the screw, and a minimum distance from the center of a fastener to the edge of any connected part as follows:

- In jurisdictions adopting the IBC: 1.5 times the diameter of the screw. When the distance to the end of the connected part is parallel to the line of the applied force, the allowable shear fastener strength determined in accordance with Section E4.3.2 of Appendix A of the AISI – NAS must be considered.
- 2. In jurisdictions adopting the UBC: three times the diameter of the screw. If the connection is subjected to shear force in one direction only, the minimum edge distance must be 1.5 times the diameter of the screw in the direction perpendicular to the force.

Screw thread length and point style are to be selected on the basis of thickness of the fastened material and thickness of the supporting steel, respectively, in accordance with the manufacturer's published installation instructions.

4.2 Installation:

Installation of the Hilti Kwik-Pro Self-drilling Screws must be in accordance with the manufacturer's published installation instructions and this report. The manufacturer's published installation instructions are to be available at the jobsite at all times during installation.

The screws must be installed perpendicular to the work surface using a variable speed screw gun set to not exceed 2,500 rpm. The screw must penetrate through the supporting steel with a minimum of three threads protruding past the back side of the supporting steel.

5.0 CONDITIONS OF USE

The Hilti Kwik-Pro Self-drilling Screws described in this report comply with, or are suitable alternatives to what is specified in, those codes listed in Section 1.0 of this report, subject to the following conditions:

- **5.1** Fasteners are to be installed in accordance with the manufacturer's published installation instructions and this report. If there is a conflict between the manufacturer's published installation instructions and this report, this report governs.
- **5.2** The allowable loads specified in Section 4.1 are not to be increased when the fasteners are used to resist wind or seismic forces.
- **5.3** The utilization of the nominal strength values contained in this evaluation report, for the design of cold-formed steel diaphragms, is outside the scope of this report.

*Corrected May 2007

ESREPORTS^{**} are not to be construed as representing aesthetics or any other attributes not specifically addressed, nor are they to be construed as an endorsement of the subject of the report or a recommendation for its use. There is no warranty by ICC Evaluation Service, Inc., express or implied, as to any finding or other matter in this report, or as to any product covered by the report.

5.4 Drawings and calculations verifying compliance with this report and the applicable code must be submitted to the code official for approval. The drawings and calculations are to be prepared by a registered design professional when required by the statutes of the jurisdiction in which the project is to be constructed.

6.0 EVIDENCE SUBMITTED

Data in accordance with the ICC-ES Acceptance Criteria for Tapping Screw Fasteners (AC118), dated December 2006.

7.0 IDENTIFICATION

Hilti Kwik-Pro Self-drilling Screws are marked with an "H" on the top of the heads, as shown in Figure 1. Packages of Hilti Self-drilling Screws are labeled with the report holder's name (Hilti, Inc.), the fastener type and size, and the evaluation report number (ESR-2196).

#1 <u>2-14,</u> #12-24	0.216	99	132	165	207	248	289	373
1/4-14	0.250	115	153	191	239	287	333	430

For SI: 1 inch = 25.4 mm, 1 lbf = 4.4 N, 1 ksi = 6.89 MPa.

¹For tension connections, the lower of the allowable pull-out, pullover, and tension fastener strength of screw found in Tables 2, 3, and 4, respectively must be used for design.

²ANSI/ASME standard screw diameters were used in the calculations and are listed in the tables.

³The allowable pull-out capacity for other member thicknesses can be determined by interpolating within the table.

⁴To calculate LRFD values, multiply values in table by the ASD safety factor of 3.0 and multiply again with the LRFD Φ factor of 0.5.

⁵For $F_u = 65$ ksi steel, multiply values by 1.44.
